Docs. Get started with building and running **jscodeshift** codemods. Get started GitHub. Read more

AI Overview

jscodeshift is a toolkit created by Facebook for running automated code-rewriting scripts (codemods) across multiple JavaScript or TypeScript files. GitHub +2

How It Works

- **Abstract Syntax Tree (AST):** It parses source code into a structured AST using recast, allowing you to query and manipulate code as objects rather than fragile strings or regex. jscodeshift.com +1
- **Style Preservation:** recast attempts to keep original code styling, indentation, and formatting intact when generating the output source. GitHub
- **Runner CLI:** It includes a command-line runner that handles file discovery, parallel processing across directories, and summary reporting of changed files. GitHub +1

Common Use Cases

- **API Migrations:** Automatically updating component props, method names, or imports across large codebases. Toptal +1
- **Framework Upgrades:** Transitioning code to newer versions of libraries (such as React or TypeScript) without manual find-and-replace. NPM +1
- **Enforcing Standards:** Standardizing code patterns and lint rules across multiple repositories. Toptal

Basic Usage

1. Installation

bash

```
npm install -g jscodeshift
# Or run on-demand via npx
npx jscodeshift -t transform.js src/
```

Use code with caution.

2. Basic Transform File (`transform.js`)

javascript

```
module.exports = function transformer(file, api) {
  const j = api.jscodeshift;
  return j(file.source)
    .find(j.Identifier, { name: 'oldName' })
    .replaceWith(j.identifier('newName'))
    .toSource();
};
```

Use code with caution.

Would you like to see ↪ **an example codemod for a specific refactoring task** (like renaming a component or changing an import), or do you need help ↪ **debugging a custom transform**?
