Automate Updating Dependencies

Learn how to use Nx migrate to **automatically update package dependencies, configuration files, and source code** to match new package versions.

How Nx migrate works | Migration steps | Configure migrate defaults

AI Overview

The `nx migrate` command automates updating your Nx workspace and plugins through the official Nx CLI Command Reference. It runs in two distinct phases: generating version updates and package changes, followed by executing the actual code and config transformations. Nx.dev +1

Standard Migration Steps

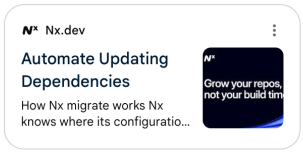

- **Generate Updates**: Run `npx nx migrate latest` (or specify a target version) to analyze your workspace, update `package.json`, and generate a `migrations.json` file. Nx.dev +2
- **Install Packages**: Install the updated dependencies using your package manager (`npm install`, `yarn`, `pnpm`, or `bun`). Nx.dev +2
- **Run Migrations**: Execute `npx nx migrate --run-migrations` to apply code and configuration changes across your projects. Nx.dev +1
- **Clean Up**: Review your git diff, test your application, and delete the temporary `migrations.json` file. Nx.dev +1

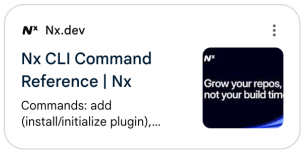

Common Options & Alternatives

- **Target Version**: Pass a specific version like `npx nx migrate 18.0.0` instead of `latest`. Nx.dev +1
- **Visual UI**: Use the **Nx Console** extension in VS Code or Cursor to run migrations via a dedicated sidebar UI.
- **Granular Control**: Use `--include=required` or `--create-commits` flags for more isolated or multi-major step updates.

If you are running into an issue, let me know:

- **What version** of Nx you are currently on and what version you are trying to reach
- **Any error messages** or failing checks during `npm install` or `--run-migrations`
